## The motion of a single water ligand ...

... around a peptide bond in acetanilide was probed in real time by time-resolved IR spectroscopy. In their Communication on page 6604 ff., O. Dopfer, M. Fujii et al. observe that triggered by photo-ionization, the H<sub>2</sub>O ligand is released from the CO site of the peptide linkage and trapped after a migration time of 5 ps at the NH site of the same peptide bond. The migration occurs via an intermediate in which the H<sub>2</sub>O molecule binds neither to the CO nor the NH site.
